# Razborov's theorem, interpolation method, and lower bounds for Resolution and Cutting Planes

Author: Alisa Knizel

< ロ > < 同 > < 回 > < 回 >

- Proof of Razborov's theorem.
- Lower bounds for the resolution proof system.
- Lower bounds for the cutting planes.

(日) (同) (三) (

# Monotone circuits

Definition Boolean circuit :

- directed acyclic graph
- nodes (gates) labelled by: inputs, AND, OR, NOT
- computes a function of its n input bit in the natural way

Conjecture: NP-complete problems have no polynomial circuits.

- the best lower bounds we are able to prove are *kn* (for small constants *k*)
- let's prove in a weaker circuit model
- the most natural model is the monotone circuits (that is, ones without NOT gates)

# Monotone circuits

- Monotone circuits can only compute monotone functions(
   x ≤ y ⇒ f(x) ≤ f(y)), and ∀ monotone function can be computed by monotone circuit.
- There are monotone NP-complete problems  $(CLIQUE_{n,k})$

< ロ > < 同 > < 回 > < 回 >

**Definition**:  $CLIQUE_{n,k}$  is the Boolean function. CLIQUE(G(V, E))=1 if G has a clique of size k.

- $CLIQUE_{n,k}$  is a monotone function.
- *CLIQUE<sub>n,k</sub>* is **NP**-complete

イロト 不得下 イヨト イヨト

# Monotone circuit for $CLIQUE_{n,k}$

- input gate  $g_{[i,j]}$  is set to true  $\Leftrightarrow [i,j] \in E$
- $\forall S \subseteq V$  with |S| = k test with AND gates whether S forms a clique
- repeat  $\forall S \subseteq V$  with |S| = k and take a big OR of the outcomes

**Definition:** Crude circuit is a circuit testing whether a family of subsets of V form a clique and returning true  $\Leftrightarrow$  one of the sets does. The above circuit is denoted  $CC(S_1, ...S_{\binom{n}{k}})$ 

**Razborov's Theorem:** There is a constant **c** such that for large enough *n* all monotone circuits for  $CLIQUE_{n,k}$  with  $k = \sqrt[4]{n}$  have size at least  $2^{c\sqrt[8]{n}}$ 

イロト イポト イヨト イヨト

- approximate any monotone circuit for *CLIQUE<sub>n,k</sub>* by a restricted kind of crude circuit.
- show that each step introduces rather few errors
- show that the resulting crude circuit has exponentially many errors.
- Thus the approximation takes exponentially many steps  $\Rightarrow$  the original monotone circuit has exponentially many gates.

- **Defenition:** A sunflower is a family of p sets  $\{P_1, ..., P_p\}$ , called *petals*, each of cardinality at most  $\ell$ , such that all pairs of sets in the family have the same intersection (called *the core* of sunflower).
- The Erdös-Rado Lemma: Let Z be a family of more than  $M = (p-1)^{\ell} \ell!$  nonempty sets, each of cardinality  $\ell$  or less. Then Z must contain a sunflower.

イロト 不得下 イヨト イヨト 三日

Induction on  $\ell$ .

- $\ell = 1 \Leftrightarrow$  different singletons form a sunflower. D is a maximal subset of Z of disjoint sets.
- $|D| \ge p$  sets, then it constitutes a sunflower with empty core.
- $\mathbf{F} = \bigcup H_i, H_i \in \mathbf{D}$ . We know:  $|\mathbf{F}| \leq (p-1)\ell$  and that  $\mathbf{D}$  intersects every set in  $\mathbf{Z}$ .
- There is an element  $d \in \mathbf{D}$  which intersects more than  $\frac{M}{(p-1)\ell} = (p-1)^{\ell}(\ell-1)!$  sets.

イロト 不得下 イヨト イヨト 二日

• 
$$\mathbf{G} = {\mathbf{S} - d : \mathbf{S} \in \mathbf{Z} \text{ and } d \in \mathbf{Z}}$$

- G has more than (p − 1)<sup>ℓ</sup>(ℓ − 1)! sets ⇒ by induction it contains a sunflower P<sub>1</sub>, ..., P<sub>p</sub>. Then {P<sub>1</sub> ∪ {d}, ..., P<sub>p</sub> ∪ {d}} is a sunflower in Z. □
- Definition: Plucking a sunflower entails replacing the sets in the sunflower by its core.

$$Z_1, .., Z_p \longrightarrow Z$$

• **Remark:**If there are >M sets in a family, we can reduce their number by repeatedly finding a sunflower and plucking it.

- do it inductively (any monotone circuit is considered as the OR or AND of two subcircuits).
- there are two circuits CC(X), CC(Y), X,Y are families of ≤ M sets of nodes. (M = (p − 1)<sup>ℓ</sup>ℓ! (p is about <sup>8</sup>√n )).
- each set with  $\leq \ell \ (= \sqrt[8]{n})$  nodes.

イロト イポト イヨト イヨト 三日

# **Approximation steps**

- $A[CC(X) \lor CC(Y)] = CC(pluck(X \cup Y))$
- A[CC(X)  $\land$  CC(Y)] = CC(pluck ({ $U_i \cup V_j : U_i \in X, V_i \in Y$ , and  $|U_i \cup V_j| \le \ell$ }))

# Positive and negative examples

- Definition: A positive example is simply a graph with {k \choose 2} edges connecting k nodes in all possible ways. There are {n \choose k} such graphs, and they all should elicit the "true".
- The negative examples are outcomes of following experiment: color the nodes with k - 1 different colors. Then join by an edge any two nodes that are colored differently. Such a graph has no k-clique. There are  $(k - 1)^n$  negative examples overall.

# False negatives and false positives

- E is a positive example. CC<sub>1</sub>(E) = true, CC = A[CC<sub>1</sub> ∨ CC<sub>2</sub>] and CC(E) = false ⇒ the approximation step has introduced a false negative.
- N is a negative example.
   CC<sub>1</sub>(N) = false, CC<sub>2</sub>(N) = false, CC = A[CC<sub>1</sub> ∨ CC<sub>2</sub>] and
   CC(N) = true ⇒ the approximation step has introduced a false positive.
- E is a positive example.
   CC<sub>1</sub>(E) = true, CC<sub>2</sub>(N) = true, CC = A[CC<sub>1</sub> ∧ CC<sub>2</sub>] and
   CC(E) = false ⇒ the approximation step has introduced a false negative.
- N is a negative example. CC<sub>1</sub>(N) = false, CC = (AND)A[CC<sub>1</sub> ∧ CC<sub>2</sub>] and CC(N) = true ⇒ the approximation step has introduced a false positive.

**Lemma:** Each approximation step introduces  $\leq M^2 2^{-p} (k-1)^n$  false positives.

#### Proof: First for an OR.

A false positive introduced by plucking (the replacement of sunflower  $\{Z_1, ..., Z_p\}$  by its core **Z**) is a coloring such that there is a pair of identically colored nodes in each petal, but at least one node from each petal was plucked away. Let's count such colorings.

< ロ > < 同 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < 回 > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ >

 $\mathsf{R}(\mathsf{X})$  is the probability of the event that there are repeated colors in set  $\mathsf{X}.$  We have:

 $\operatorname{\mathsf{prob}}[R(Z_1) \wedge ... \wedge R(Z_\rho) \wedge \neg R(Z)] \leq \operatorname{\mathsf{prob}}[R(Z_1) \wedge ... \wedge R(Z_\rho) | \neg R(Z)] =$ 

 $\mathsf{R}(\mathsf{X})$  is the probability of the event that there are repeated colors in set  $\mathsf{X}.$  We have:

 $\operatorname{\mathsf{prob}}[R(Z_1) \wedge ... \wedge R(Z_\rho) \wedge \neg R(Z)] \leq \operatorname{\mathsf{prob}}[R(Z_1) \wedge ... \wedge R(Z_\rho) | \neg R(Z)] =$ 

 $\mathsf{R}(\mathsf{X})$  is the probability of the event that there are repeated colors in set  $\mathsf{X}.$  We have:

 $\operatorname{\mathsf{prob}}[R(Z_1) \wedge ... \wedge R(Z_\rho) \wedge \neg R(Z)] \leq \operatorname{\mathsf{prob}}[R(Z_1) \wedge ... \wedge R(Z_\rho) | \neg R(Z)] =$ 

$$=\prod_{i=1}^{p} \operatorname{prob}[R(Z_i)|\neg R(Z)] \leq \prod_{i=1}^{p} \operatorname{prob}[R(Z_i)]$$

# **Proof(OR)**:

• Consider two nodes in  $Z_i$ , prob[they have the same color] $=\frac{1}{k-1}$ . Then

$$\operatorname{prob}[R(Z_i)] \leq \frac{\binom{|Z_i|}{2}}{k-1} \leq \frac{\binom{\ell}{2}}{k-1} \leq \frac{1}{2}$$

- Thus the probability that a randomly chosen coloring is a new false negative is at most 2<sup>-p</sup>
- There are  $(k-1)^n$  different coloring  $\Rightarrow$  each plucking introduces  $\leq 2^{-p}(k-1)^n$  false positives. The approximation step entails up to  $\frac{2M}{p-1}$  pluckings, the lemma holds for the OR approximation step.

イロト 不得下 イヨト イヨト 三日

Consider now an AND approximation step. It can be broken down in 3 phases:

- we form  $CC(\{U \cup V : U \in X, V \in Y\}) \rightarrow$  no false positives.
- $\bullet$  the second phase omits from the approximator circuit several sets  $\rightarrow$  no false positives.
- the third phase entails a sequence  $\langle M^2 \rangle$  pluckings, during each of which  $\leq 2^{-p}(k-1)^n$  false positives are introduced.  $\Box$

イロト 不得下 イヨト イヨト 三日

# Lemma 2(about false negatives)

- Lemma: Each approximation step introduce ≤ M<sup>2</sup> (<sup>n-ℓ-1</sup><sub>k-ℓ-1</sub>) false negatives.
- Proof:
- plucking can introduce no false negatives
- $\Rightarrow$  the approximation of an OR introduces no false negatives.
- Consider now an AND approximation step.
- when we form  $CC(\{U \cup V : U \in \mathbf{X}, V \in \mathbf{Y}\})$  no f. n. can be introduced.

# **Proof:**

- each deletion of a set W which is larger than  $\ell$  can introduce several false negatives, namely the cliques that contain  $W \Rightarrow$  at most  $\binom{n-\ell-1}{k-\ell-1}$  f. n. can be introduced by each deletion.
- there are at most  $M^2$  sets to be deleted.  $\Box$

# Conclusion

Lemma 1 and 2 show that each approximation step introduces "few"false positives and false negatives. We'll next show that the resulting crude circuit must have "a lot".

(日) (同) (三) (三)

**Lemma 3:** Every crude circuit is not identically **false**(and thus is wrong on all positive examples), or outputs **true** on at least half of the negative examples.

- If the crude circuit is not identically false, then it accepts at least those graphs that have a clique on some set X of nodes, with |X| ≤ ℓ.
- But from Lemma 1 at least half of the colorings assign different colors to the nodes of X ⇒ half of the negative examples have a clique at X and are accepted. □

## The last step of the proof of Razborov's theorem:

• 
$$p = \sqrt[8]{n} \log n, \ \ell = \sqrt[8]{n} \Rightarrow$$

$$M = (p-1)^{\ell} \ell! < n^{\frac{1}{3}\sqrt[6]{n}}$$

for large enough n.

- If the final crude circuit is identically false⇒ all possitive examples were introduced as false negatives at some step
- $\Rightarrow$  the original monotone circuit for  $CLIQUE_{n,k}$  had  $\leq$  (Lemma 2)

$$\frac{\binom{n}{k}}{M^2\binom{n-\ell-1}{k-\ell-1}}$$

$$\geq \frac{1}{M^2(\frac{n-\ell}{k})^\ell} \geq n^{c\sqrt[3]{n}},$$

with  $c = \frac{1}{12}$ 

Alisa Knizel ()

# The proof of Razborov's theorem:

- Lemma 3 states that there are  $\geq \frac{1}{2}(k-1)^n$  false positives, each approximation step introduces  $\leq M^2 2^{-p}(k-1)^n$  (Lemma 1) of them.
- $\Rightarrow$  the original monotone circuit had at least  $2^{p-1}M^{-2} > n^{c\sqrt[8]{n}}$ , with  $c = \frac{1}{3}$ .

**Definition** The propositional resolution proof system is the one which uses elementary disjunctions i. e., disjunctions of literals, as formulas, and the cut rule as the only one rule

$$\frac{\Gamma \lor p, \Delta \lor \neg p}{\Gamma \lor \Delta}$$

Where  $\Gamma, \Delta$  are elementary disjunctions.

## Effective interpolation for Resolution

The ternary connective sel (selector) is defined by sel(0, x, y) = x and sel(1, x, y) = y

Theorem 1: Let P be a resolution proof of the empty clause from clauses A<sub>i</sub>(p̄, q̄), i ∈ I, B<sub>j</sub>(p̄, r̄), j ∈ J where p̄, q̄, r̄ are disjoint sets of propositional variables. Then there exists a circuit C(p̄) such that for every 0 − 1 assignment ā for p̄

$$C(\bar{a}) = 0 \Rightarrow A_i(\bar{p}, \bar{q}), i \in I$$

are unsatisfiable, and

$$C(\bar{a}) = 1 \Rightarrow B_j(\bar{p},\bar{r}), j \in J$$

are unsatisfiable;

the circuit C is in basis  $\{0, 1, \lor, \land\}$  and its underlying graph is the graph of the proof P.

イロト 不得下 イヨト イヨト 三日

Moreover, we can construct in polynomial time a resolution proof of the empty clause from clauses  $A_i(\bar{p}, \bar{q}), i \in I$  if  $C(\bar{a}) = 0$ , respectively  $B_j(\bar{p}, \bar{r}), j \in J$  if  $C(\bar{a}) = 1$ ; the length of this proof is less than or equal to the length of P.

The transformation of the proof for a given assignment  $\bar{p} \rightarrow \bar{a}$ 

• 1. We replace each clause of *P* by a subclause so that each clause in the proof is either q-clause or r-clause. We start with initial clause, which are left unchanged and continue along the derivation *P*.

$$\frac{\Gamma \lor p_k, \Delta \lor \neg p_k}{\Gamma \lor \Delta}$$

and we have replaced  $\Gamma \lor p_k$  by  $\Gamma'$  and  $\Delta \lor \neg p_k$  by  $\Delta'$ . Then we replace  $\Gamma \lor \Delta$  by  $\Gamma'$  if  $p_k \to 0$  and by  $\Delta'$  if  $p_k \to 1$ 

### **Proof:**

• Case 2.

$$\frac{\Gamma \vee q_k, \Delta \vee \neg q_k}{\Gamma \vee \Delta}$$

and we have replaced  $\Gamma \lor q_k$  by  $\Gamma'$  and  $\Delta \lor \neg q_k$  by  $\Delta'$ . If one of  $\Gamma'$ ,  $\Delta'$  is an r-clause  $\rightarrow$  replace  $\Gamma \lor \Delta$  by this clause. If both  $\Gamma'$  and  $\Delta'$  are q-clauses  $\rightarrow$  resolve along  $q_k$ , or take one without  $q_k$ .

• Case 3.

$$\frac{\Gamma \vee r_k, \Delta \vee \neg r_k}{\Gamma \vee \Delta}$$

This is the dual case to case 2.

- 2.Delete the clauses which contain a  $\bar{p}$  literal with value 1, and remove all  $\bar{p}$  literals from the remaining clauses.
- We got a valid derivation of the final empty clause from the reduced initial clauses. If this final clause is a q-clause, the proof contains a subproof using only the reduced clauses A<sub>i</sub>, i ∈ I; if an r-clause ⇒ B<sub>j</sub>, j ∈ J

# **Proof:**

- Construction of C:
- The value computed at a gate corresponding to a clause  $\Gamma$  will determine if it is transformed into a q(r)-clause. We assign 0 to q-clauses and 1 to r-clauses.
- Put constant 0 gates on clauses A<sub>i</sub>, i ∈ I and constant 1 gates on clauses B<sub>j</sub>, j ∈ J.

- Now consider 3 cases as above.
- Case 1. If the gate on Γ ∨ pk gets value x and the gate on Δ ∨ ¬pk gets value y, then the gate on Γ ∨ Δ should get the value z = sel(pk, x, y). We place the sel gate on Γ ∨ Δ.
- Case 2. If the gate on Γ ∨ q<sub>k</sub> gets value x and the gate on Δ ∨ ¬q<sub>k</sub> gets value y, then the gate on Γ ∨ Δ should get the value z = x ∨ y). We place the ∨ gate on Γ ∨ Δ.
- Case 3. This is dual to case 2.

#### Theorem 2:

Suppose moreover that either all variables  $\bar{p}$  occur in  $A_i(\bar{p}, \bar{q}), i \in I$  only positively or all variables  $\bar{p}$  occur in  $\bar{p}$  occur in  $B_j(\bar{p}, \bar{r}), j \in J$  only negatively, then one can replace the selector connective sel by a monotone ternary connective.

イロト 不得下 イヨト イヨト 三日

- W. I. o. g. assume that all  $\bar{p}$ 's are positive in clauses  $A_i, i \in I$ .
- Hence in case 1, if Δ' is a q-clause, it cannot contain ¬p<sub>k</sub>, hence we can take it for Γ ∨ Δ, even if p<sub>k</sub> → 0.
- Thus we can replace sel(p<sub>k</sub>, x, y) by (p<sub>k</sub> ∨ x) ∧ y which is monotone and differs from selector exactly on one input (p<sub>k</sub> = 0, x = 1, y = 0) which corresponds to the above situation.

イロト イポト イヨト イヨト 三日

- We use propositional variables  $\bar{p}$  with the interpretation 0 = false, 1 = true.
- A proof line is an inequality

$$\sum_k c_k p_k \geq C$$

• Axiom:  $0 \le p_k \le 1$ 

(日) (同) (三) (三)

### The rules

- Addition:  $\sum_k c_k p_k \ge C$  and  $\sum_k d_k p_k \ge D$  $\longrightarrow \sum_k (c_k + d_k) p_k \ge C + D$
- Division:  $d > 0, d \in \mathbb{Z}, d | c_k$  and  $\sum_k c_k p_k \ge C \longrightarrow \sum_k \frac{c_k}{d} p_k \ge \lceil \frac{C}{d} \rceil$
- Multiplication:  $d > 0, d \in \mathbb{Z}$  and  $\sum_k c_k p_k \ge C \longrightarrow \sum_k dc_k p_k \ge dC$

#### Theorem 3

Theorem 3: Let P be a cutting plane proof of the contradiction

 0 ≥ 1 from inequalities ∑<sub>k</sub> c<sub>i,k</sub>p<sub>k</sub> + ∑<sub>l</sub> b<sub>i,l</sub>q<sub>l</sub> ≥ A<sub>i</sub>, i ∈ l,
 ∑<sub>k</sub> c'<sub>j,k</sub>p<sub>k</sub> + ∑<sub>m</sub> d<sub>j,m</sub>q<sub>m</sub> ≥ B<sub>j</sub>, j ∈ J where p̄, q̄, r̄ are disjoint sets of
 propositional variables. Then there exists a circuit C(p̄) such that for
 every 0 - 1 assignment ā for p̄
 C(ā) = 0 ⇒ ∑<sub>k</sub> c<sub>i,k</sub>p<sub>k</sub> + ∑<sub>l</sub> b<sub>i,l</sub>q<sub>l</sub> ≥ A<sub>i</sub>, i ∈ l are unsatisfiable, and
 C(ā) = 1 ⇒ ∑<sub>k</sub> c'<sub>j,k</sub>p<sub>k</sub> + ∑<sub>m</sub> d<sub>j,m</sub>q<sub>m</sub> ≥ B<sub>j</sub>, j ∈ J are unsatisfiable.
 The size of the circuit is polynomial in the binary length of the
 numbers A<sub>i</sub>, i ∈ l, B<sub>j</sub>, j ∈ J and the number of inequalities in P.

Moreover, we can construct in polynomial time a cutting plane proof of the contradiction  $0 \ge 1$  from inequalities  $\sum_k c_{i,k}p_k + \sum_l b_{i,l}q_l \ge A_i, i \in I$  if  $C(\bar{a}) = 0$ , respectively  $\sum_k c'_{j,k}p_k + \sum_m d_{j,m}q_m \ge B_j, j \in J$  if  $C(\bar{a}) = 1$ ; the length of this proof is less than or equal to the length of P.

イロト イ得ト イヨト イヨト 三日

## **Proof:**

Let P and assignment  $\bar{p} \rightarrow \bar{a}$  be given.

- Replace  $\sum_{k} e_{k} p_{k} + \sum_{l} f_{l} q_{l} + \sum_{l} f_{l} q_{l} \geq D \longrightarrow \sum_{l} f_{l} q_{l} \geq D_{0}, \sum_{m} g_{m} r_{m} \geq D_{1}$
- The pair is at least as strong as the original one  $D_0 + D_1 \ge D \sum_k e_k p_k$
- $\sum_{k} c_{i,k} p_k + \sum_{l} b_{i,l} q_l \ge A_i \longrightarrow$  the pair  $\sum_{l} b_{i,l} q_l \ge A_i \sum_{k} c_{i,k} p_k, 0 \ge 0$
- $\sum_{k} c'_{j,k} p_k + \sum_{m} d_{j,m} r_m \ge B_j \longrightarrow$  the pair  $\sum_{m} d_{j,m} r_m \ge B_j \sum_{k} c'_{j,k} p_k, 0 \ge 0$
- The rules are performed in parallel on the 2 inequalities in the pair.

イロト 不得下 イヨト イヨト 二日

# **Proof:**

- The pair corresponding to the last inequality  $0 \ge 1$  is  $0 \ge D_0$ ,  $0 \ge D_1$ where  $D_0 + D_1 \ge 1$
- $\Rightarrow$  D<sub>0</sub>  $\geq$  1  $\lor$  D<sub>1</sub>  $\geq$  1
- $\Rightarrow$  We have a proof of contradiction either from  $\sum_{k} c_{i,k} p_{k} + \sum_{l} b_{i,l} q_{l} \ge A_{i}, i \in I \text{ or from}$   $\sum_{k} c'_{j,k} p_{k} + \sum_{m} d_{j,m} q_{m} \ge B_{j}, j \in J .$
- Each proof P can be transformed in proof P' wich is at most polynomially longer and all the coefficients have polynomially bounded binary length (Clote and Buss).
- All D<sub>i</sub> have polynomially bounded binary length ⇒ the above procedure can be done in polynomial time in the binary length of A<sub>i</sub>, i ∈ I, B<sub>j</sub>, j ∈ J and the number of inequalities.
- We use the transformation of polynomial time algorithms into sequences of polynomial size circuits.

The End.
