

9 van Emde Boas Trees

Dynamic Set Data Structure S :

- ▶ $S.\text{insert}(x)$
- ▶ $S.\text{delete}(x)$
- ▶ $S.\text{search}(x)$
- ▶ $S.\text{min}()$
- ▶ $S.\text{max}()$
- ▶ $S.\text{succ}(x)$
- ▶ $S.\text{pred}(x)$

9 van Emde Boas Trees

Can we improve the existing algorithms when the keys are from a restricted set?

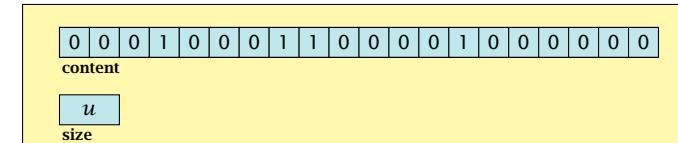

In the following we assume that the keys are from $\{0, 1, \dots, u - 1\}$, where u denotes the size of the universe.

9 van Emde Boas Trees

For this chapter we ignore the problem of storing satellite data:

- ▶ $S.\text{insert}(x)$: Inserts x into S .
- ▶ $S.\text{delete}(x)$: Deletes x from S . Usually assumes that $x \in S$.
- ▶ $S.\text{member}(x)$: Returns 1 if $x \in S$ and 0 otw.
- ▶ $S.\text{min}()$: Returns the value of the minimum element in S .
- ▶ $S.\text{max}()$: Returns the value of the maximum element in S .
- ▶ $S.\text{succ}(x)$: Returns successor of x in S . Returns null if x is maximum or larger than any element in S . Note that x needs not to be in S .
- ▶ $S.\text{pred}(x)$: Returns the predecessor of x in S . Returns null if x is minimum or smaller than any element in S . Note that x needs not to be in S .

Implementation 1: Array

one array of u bits

Use an array that encodes the indicator function of the dynamic set.

Implementation 1: Array

Algorithm 19 array.insert(x)

```
1: content[ $x$ ]  $\leftarrow$  1;
```

Algorithm 20 array.delete(x)

```
1: content[ $x$ ]  $\leftarrow$  0;
```

Algorithm 21 array.member(x)

```
1: return content[ $x$ ];
```

- ▶ Note that we assume that x is valid, i.e., it falls within the array boundaries.
- ▶ Obviously(?) the running time is constant.

Implementation 1: Array

Algorithm 22 array.max()

```
1: for ( $i = \text{size} - 1; i \geq 0; i--$ ) do
2:   if content[ $i$ ] = 1 then return  $i$ ;
3: return null;
```

Algorithm 23 array.min()

```
1: for ( $i = 0; i < \text{size}; i++$ ) do
2:   if content[ $i$ ] = 1 then return  $i$ ;
3: return null;
```

- ▶ Running time is $\mathcal{O}(u)$ in the worst case.

Implementation 1: Array

Algorithm 24 array.succ(x)

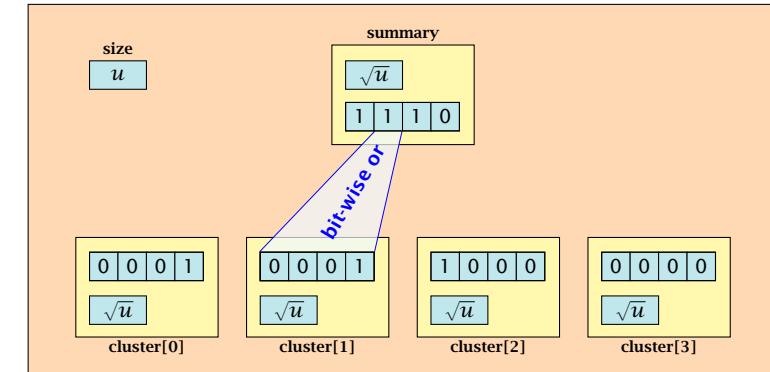

```
1: for ( $i = x + 1; i < \text{size}; i++$ ) do
2:   if content[ $i$ ] = 1 then return  $i$ ;
3: return null;
```

Algorithm 25 array.pred(x)

```
1: for ( $i = x - 1; i \geq 0; i--$ ) do
2:   if content[ $i$ ] = 1 then return  $i$ ;
3: return null;
```

- ▶ Running time is $\mathcal{O}(u)$ in the worst case.

Implementation 2: Summary Array

- ▶ \sqrt{u} cluster-arrays of \sqrt{u} bits.
- ▶ One summary-array of \sqrt{u} bits. The i -th bit in the summary array stores the bit-wise or of the bits in the i -th cluster.

Implementation 2: Summary Array

The bit for a key x is contained in cluster number $\left\lfloor \frac{x}{\sqrt{u}} \right\rfloor$.

Within the cluster-array the bit is at position $x \bmod \sqrt{u}$.

For simplicity we assume that $u = 2^{2k}$ for some $k \geq 1$. Then we can compute the cluster-number for an entry x as $\text{high}(x)$ (the upper half of the dual representation of x) and the position of x within its cluster as $\text{low}(x)$ (the lower half of the dual representation).

Implementation 2: Summary Array

Algorithm 28 delete(x)

```
1: cluster[high(x)].delete(low(x));  
2: if cluster[high(x)].min() = null then  
3:   summary.delete(high(x));
```

- ▶ The running time is dominated by the cost of a minimum computation, which will turn out to be $\mathcal{O}(\sqrt{u})$.

Implementation 2: Summary Array

Algorithm 26 member(x)

```
1: return cluster[high(x)].member(low(x));
```

Algorithm 27 insert(x)

```
1: cluster[high(x)].insert(low(x));  
2: summary.insert(high(x));
```

- ▶ The running times are constant, because the corresponding array-functions have constant running times.

Implementation 2: Summary Array

Algorithm 29 max()

```
1: maxcluster ← summary.max();  
2: if maxcluster = null return null;  
3: offs ← cluster[maxcluster].max()  
4: return maxcluster ∘ offs;
```

The operator \circ stands for the concatenation of two bitstrings.
This means if $x = 0111_2$ and $y = 0001_2$ then $x \circ y = 01110001_2$.

Algorithm 30 min()

```
1: mincluster ← summary.min();  
2: if mincluster = null return null;  
3: offs ← cluster[mincluster].min()  
4: return mincluster ∘ offs;
```

- ▶ Running time is roughly $2\sqrt{u} = \mathcal{O}(u)$ in the worst case.

Implementation 2: Summary Array

Algorithm 31 succ(x)

```
1:  $m \leftarrow \text{cluster}[\text{high}(x)].\text{succ}(\text{low}(x))$ 
2: if  $m \neq \text{null}$  then return  $\text{high}(x) \circ m$ ;
3:  $\text{succcluster} \leftarrow \text{summary}.\text{succ}(\text{high}(x))$ ;
4: if  $\text{succcluster} \neq \text{null}$  then
5:    $\text{offs} \leftarrow \text{cluster}[\text{succcluster}].\text{min}()$ ;
6:   return  $\text{succcluster} \circ \text{offs}$ ;
7: return null;
```

- ▶ Running time is roughly $3\sqrt{u} = \mathcal{O}(\sqrt{u})$ in the worst case.

Implementation 2: Summary Array

Algorithm 32 pred(x)

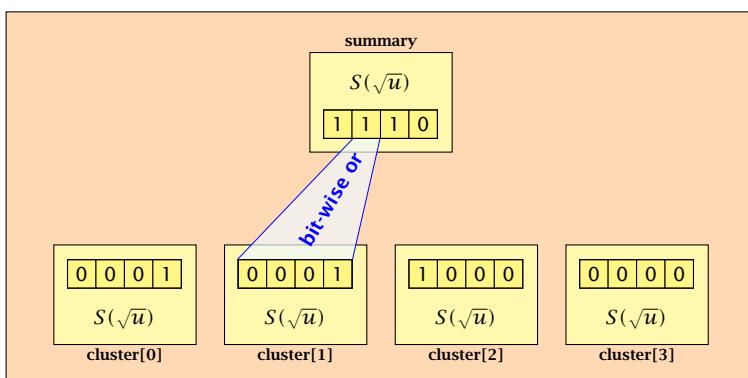

```
1:  $m \leftarrow \text{cluster}[\text{high}(x)].\text{pred}(\text{low}(x))$ 
2: if  $m \neq \text{null}$  then return  $\text{high}(x) \circ m$ ;
3:  $\text{predcluster} \leftarrow \text{summary}.\text{pred}(\text{high}(x))$ ;
4: if  $\text{predcluster} \neq \text{null}$  then
5:    $\text{offs} \leftarrow \text{cluster}[\text{predcluster}].\text{max}()$ ;
6:   return  $\text{predcluster} \circ \text{offs}$ ;
7: return null;
```

- ▶ Running time is roughly $3\sqrt{u} = \mathcal{O}(\sqrt{u})$ in the worst case.

Implementation 3: Recursion

Instead of using sub-arrays, we build a recursive data-structure.

$S(u)$ is a dynamic set data-structure representing u bits:

Implementation 3: Recursion

We assume that $u = 2^{2k}$ for some k .

The data-structure $S(2)$ is defined as an array of 2-bits (end of the recursion).

Implementation 3: Recursion

The code from Implementation 2 can be used **unchanged**. We only need to redo the analysis of the running time.

Note that in the code we do not need to specifically address the non-recursive case. This is achieved by the fact that an $S(4)$ will contain $S(2)$'s as sub-datastructures, which are **arrays**. Hence, a call like `cluster[1].min()` from within the data-structure $S(4)$ is **not** a recursive call as it will call the function `array.min()`.

This means that the non-recursive case is been dealt with while initializing the data-structure.

Implementation 3: Recursion

Algorithm 34 insert(x)

```
1: cluster[high( $x$ )].insert(low( $x$ ));  
2: summary.insert(high( $x$ ));
```

$$\triangleright T_{\text{ins}}(u) = 2T_{\text{ins}}(\sqrt{u}) + 1.$$

Implementation 3: Recursion

Algorithm 33 member(x)

```
1: return cluster[high( $x$ )].member(low( $x$ ));
```

$$\triangleright T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1.$$

Implementation 3: Recursion

Algorithm 35 delete(x)

```
1: cluster[high( $x$ )].delete(low( $x$ ));  
2: if cluster[high( $x$ )].min() = null then  
3:   summary.delete(high( $x$ ));
```

$$\triangleright T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\text{min}}(\sqrt{u}) + 1.$$

Implementation 3: Recursion

Algorithm 36 min()

```
1: mincluster  $\leftarrow$  summary.min();  
2: if mincluster = null return null;  
3: offs  $\leftarrow$  cluster[mincluster].min();  
4: return mincluster  $\circ$  offs;
```

► $T_{\min}(u) = 2T_{\min}(\sqrt{u}) + 1.$

Implementation 3: Recursion

$$T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1:$$

Set $\ell := \log u$ and $X(\ell) := T_{\text{mem}}(2^\ell)$. Then

$$\begin{aligned} X(\ell) &= T_{\text{mem}}(2^\ell) = T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1 \\ &= T_{\text{mem}}(2^{\frac{\ell}{2}}) + 1 = X(\frac{\ell}{2}) + 1 . \end{aligned}$$

Using Master theorem gives $X(\ell) = \mathcal{O}(\log \ell)$, and hence $T_{\text{mem}}(u) = \mathcal{O}(\log \log u)$.

Implementation 3: Recursion

Algorithm 37 succ(x)

```
1: m  $\leftarrow$  cluster[high(x)].succ(low(x))  
2: if m  $\neq$  null return high(x)  $\circ$  m;  
3: succcluster  $\leftarrow$  summary.succ(high(x));  
4: if succcluster  $\neq$  null then  
5:   offs  $\leftarrow$  cluster[succcluster].min();  
6:   return succcluster  $\circ$  offs;  
7: return null;
```

► $T_{\text{succ}}(u) = 2T_{\text{succ}}(\sqrt{u}) + T_{\min}(\sqrt{u}) + 1.$

Implementation 3: Recursion

$$T_{\text{ins}}(u) = 2T_{\text{ins}}(\sqrt{u}) + 1.$$

Set $\ell := \log u$ and $X(\ell) := T_{\text{ins}}(2^\ell)$. Then

$$\begin{aligned} X(\ell) &= T_{\text{ins}}(2^\ell) = T_{\text{ins}}(u) = 2T_{\text{ins}}(\sqrt{u}) + 1 \\ &= 2T_{\text{ins}}(2^{\frac{\ell}{2}}) + 1 = 2X(\frac{\ell}{2}) + 1 . \end{aligned}$$

Using Master theorem gives $X(\ell) = \mathcal{O}(\ell)$, and hence $T_{\text{ins}}(u) = \mathcal{O}(\log u)$.

The same holds for $T_{\max}(u)$ and $T_{\min}(u)$.

Implementation 3: Recursion

$$T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + T_{\text{min}}(\sqrt{u}) + 1 = 2T_{\text{del}}(\sqrt{u}) + \Theta(\log u).$$

Set $\ell := \log u$ and $X(\ell) := T_{\text{del}}(2^\ell)$. Then

$$\begin{aligned} X(\ell) &= T_{\text{del}}(2^\ell) = T_{\text{del}}(u) = 2T_{\text{del}}(\sqrt{u}) + \Theta(\log u) \\ &= 2T_{\text{del}}(2^{\frac{\ell}{2}}) + \Theta(\ell) = 2X(\frac{\ell}{2}) + \Theta(\ell). \end{aligned}$$

Using Master theorem gives $X(\ell) = \Theta(\ell \log \ell)$, and hence $T_{\text{del}}(u) = \mathcal{O}(\log u \log \log u)$.

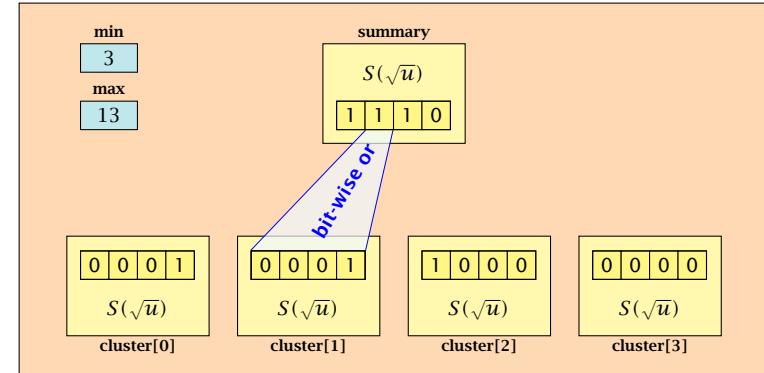

The same holds for $T_{\text{pred}}(u)$ and $T_{\text{succ}}(u)$.

Implementation 4: van Emde Boas Trees

Advantages of having max/min pointers:

- ▶ Recursive calls for min and max are constant time.
- ▶ $\text{min} = \text{null}$ means that the data-structure is empty.
- ▶ $\text{min} = \text{max} \neq \text{null}$ means that the data-structure contains exactly one element.
- ▶ We can insert into an empty datastructure in constant time by only setting $\text{min} = \text{max} = x$.
- ▶ We can delete from a data-structure that just contains one element in constant time by setting $\text{min} = \text{max} = \text{null}$.

Implementation 4: van Emde Boas Trees

- ▶ The bit referenced by **min** is **not** set within sub-datastructures.
- ▶ The bit referenced by **max** **is** set within sub-datastructures (if $\text{max} \neq \text{min}$).

Implementation 4: van Emde Boas Trees

Algorithm 38 max()

1: **return** max;

Algorithm 39 min()

1: **return** min;

- ▶ Constant time.

Implementation 4: van Emde Boas Trees

Algorithm 40 member(x)

```
1: if  $x = \min$  then return 1; // TRUE  
2: return cluster[high( $x$ )].member(low( $x$ ));
```

- ▶ $T_{\text{mem}}(u) = T_{\text{mem}}(\sqrt{u}) + 1 \Rightarrow T(u) = \mathcal{O}(\log \log u)$.

Implementation 4: van Emde Boas Trees

Algorithm 42 insert(x)

```
1: if  $\min = \text{null}$  then  
2:    $\min = x$ ;  $\max = x$ ;  
3: else  
4:   if  $x < \min$  then exchange  $x$  and  $\min$ ;  
5:   if cluster[high( $x$ )].min = null; then  
6:     summary.insert(high( $x$ ));  
7:     cluster[high( $x$ )].insert(low( $x$ ));  
8:   else  
9:     cluster[high( $x$ )].insert(low( $x$ ));  
10:  if  $x > \max$  then  $\max = x$ ;
```

- ▶ $T_{\text{ins}}(u) = T_{\text{ins}}(\sqrt{u}) + 1 \Rightarrow T_{\text{ins}}(u) = \mathcal{O}(\log \log u)$.

Implementation 4: van Emde Boas Trees

Algorithm 41 succ(x)

```
1: if  $\min \neq \text{null} \wedge x < \min$  then return  $\min$ ;  
2:  $\maxincluster \leftarrow \text{cluster}[\text{high}(x)].\max()$ ;  
3: if  $\maxincluster \neq \text{null} \wedge \text{low}(x) < \maxincluster$  then  
4:    $\text{offs} \leftarrow \text{cluster}[\text{high}(x)].\text{succ}(\text{low}(x))$ ;  
5:   return  $\text{high}(x) \circ \text{offs}$ ;  
6: else  
7:    $\text{succcluster} \leftarrow \text{summary}.\text{succ}(\text{high}(x))$ ;  
8:   if  $\text{succcluster} = \text{null}$  then return  $\text{null}$ ;  
9:    $\text{offs} \leftarrow \text{cluster}[\text{succcluster}].\min()$ ;  
10:  return  $\text{succcluster} \circ \text{offs}$ ;
```

- ▶ $T_{\text{succ}}(u) = T_{\text{succ}}(\sqrt{u}) + 1 \Rightarrow T_{\text{succ}}(u) = \mathcal{O}(\log \log u)$.

Implementation 4: van Emde Boas Trees

Implementation 4: van Emde Boas Trees

Note that the recursive call in Line 7 takes constant time as the if-condition in Line 5 ensures that we are inserting in an empty sub-tree.

The only non-constant recursive calls are the call in Line 6 and in Line 9. These are mutually exclusive, i.e., only one of these calls will actually occur.

From this we get that $T_{\text{ins}}(u) = T_{\text{ins}}(\sqrt{u}) + 1$.

Implementation 4: van Emde Boas Trees

- ▶ Assumes that x is contained in the structure.

Algorithm 43 delete(x)

```

1: if min = max then
2:   min = null; max = null;
3: else
4:   if  $x = \min$  then          find new minimum
5:     firstcluster ← summary.min();
6:     offs ← cluster[firstcluster].min();
7:      $x \leftarrow \text{firstcluster} \circ \text{offs}$ ;
8:     min ←  $x$ ;
9:   cluster[high( $x$ )].delete(low( $x$ ));      delete
                                         continued...

```

Implementation 4: van Emde Boas Trees

Note that only one of the possible recursive calls in Line 9 and Line 11 in the deletion-algorithm may take non-constant time.

To see this observe that the call in Line 11 only occurs if the cluster where x was deleted is now empty. But this means that the call in Line 9 deleted the last element in cluster[high(x)]. Such a call only takes constant time.

Hence, we get a recurrence of the form

$$T_{\text{del}}(u) = T_{\text{del}}(\sqrt{u}) + c .$$

This gives $T_{\text{del}}(u) = \mathcal{O}(\log \log u)$.

Implementation 4: van Emde Boas Trees

Algorithm 43 delete(x)

	...continued	fix maximum
10:	if cluster[high(x)].min() = null then	
11:	summary.delete(high(x));	
12:	if $x = \max$ then	
13:	summax ← summary.max();	
14:	if summax = null then $\max \leftarrow \min$;	
15:	else	
16:	offs ← cluster[summax].max();	
17:	$\max \leftarrow \text{summax} \circ \text{offs}$	
18:	else	
19:	if $x = \max$ then	
20:	offs ← cluster[high(x)].max();	
21:	$\max \leftarrow \text{high}(x) \circ \text{offs};$	

9 van Emde Boas Trees

Space requirements:

- ▶ The space requirement fulfills the recurrence
- $$S(u) = (\sqrt{u} + 1)S(\sqrt{u}) + \mathcal{O}(\sqrt{u}) .$$
- ▶ Note that we cannot solve this recurrence by the Master theorem as the branching factor is not constant.
 - ▶ One can show by induction that the space requirement is $S(u) = \mathcal{O}(u)$. Exercise.
