4.3 Divide & Conquer — Merging

Given two sorted sequences $A = (a_1 \dots a_n)$ and $B = (b_1 \dots b_n)$, compute the sorted squence $C = (c_1 \dots c_n)$.

Observation:

PA © Harald Räcke

We can assume wlog. that elements in A and B are different.

Then for $c_i \in C$ we have $i = \operatorname{rank}(c_i : A \cup B)$.

This means we just need to determine $rank(x : A \cup B)$ for all elements!

Observe, that $rank(x : A \cup B) = rank(x : A) + rank(x : B)$.

Clearly, for $x \in A$ we already know rank(x : A), and for $x \in B$ we know rank(x : B).

4.3 Divide & Conquer — Merging

Compute rank(x : A) for all $x \in B$ and rank(x : B) for all $x \in A$. can be done in $O(\log n)$ time with 2n processors by binary search

Lemma 3

On a CREW PRAM, Merging can be done in $O(\log n)$ time and $O(n \log n)$ work.

not optimal

PA © Harald Räcke 4.3 Divide & Conquer — Merging

4.3 Divide & Conquer — Merging

We can generate the subproblems in time $O(\log n)$ and work O(n).

Note that in a sub-problem B_i has length $\log n$.

If we run the algorithm again for every subproblem, (where A_i takes the role of B) we can in time $\mathcal{O}(\log \log n)$ and work $\mathcal{O}(n)$ generate subproblems where A_j and B_j have both length at most $\log n$.

Such a subproblem can be solved by a single processor in time $O(\log n)$ and work $O(|A_i| + |B_i|)$.

Parallelizing the last step gives total work $\mathcal{O}(n)$ and time $\mathcal{O}(\log n)$.

the resulting algorithm is work optimal

4.6 Symmetry Breaking

The following algorithm colors an n-node cycle with $\lceil \log n \rceil$ colors.

Algorithm 9 BasicColoring1: for $1 \le i \le n$ pardo2: $col(i) \leftarrow i$ 3: $k_i \leftarrow$ smallest bitpos where col(i) and col(S(i)) differ4: $col'(i) \leftarrow 2k_i + col(i)_{k_i}$

(bit positions are numbered starting with 0)

4.5 Inserting into a (2, 3)-tree

- Step 3, works in phases; one phase for every level of the tree
- Step 4, works in rounds; in each round a different set of elements is inserted

Observation

We can start with phase *i* of round *r* as long as phase *i* of round r - 1 and (of course), phase i - 1 of round *r* has finished.

This is called Pipelining. Using this technique we can perform all rounds in Step 4 in just $O(\log k + \log n)$ many parallel steps.

PA © Harald Räcke 4.5 Inserting into a (2,3)-tree

61

PA © Harald Räcke

4.6 Symmetry Breaking

Applying the algorithm to a coloring with bit-length t generates a coloring with largest color at most

$$2(t-1) + 1$$

and bit-length at most

 $\lceil \log_2(2(t-1)+1) \rceil \le \lceil \log_2(2t) \rceil = \lceil \log_2(t) \rceil + 1$

Applying the algorithm repeatedly generates a constant number of colors after $O(\log^* n)$ operations.

Note that the first inequality holds because 2(t-1) - 1 is odd.

© Harald Räcke
```

```
4.6 Symmetry Breaking
```

4.6 Symmetry Breaking

Lemma 8

Given n integers in the range $0, ..., O(\log n)$, there is an algorithm that sorts these numbers in $O(\log n)$ time using a linear number of operations.

Proof: Exercise!

| ym | metry Breaking |
|-----|---|
| | |
| Alg | orithm 11 OptColor |
| 1: | for $1 \le i \le n$ pardo |
| 2: | $\operatorname{col}(i) \leftarrow i$ |
| 3: | apply BasicColoring once |
| 4: | sort vertices by colors |
| 5: | for $\ell = 2\lceil \log n \rceil$ to 3 do |
| 6: | for all vertices <i>i</i> of color ℓ pardo |
| 7: | $\operatorname{col}(i) \leftarrow \min\{\{0, 1, 2\} \setminus \{\operatorname{col}(P[i]), \operatorname{col}(S[i])\}\}$ |

We can perform Lines 6 and 7 in time $\mathcal{O}(n_\ell)$ only because we sorted before. In general a statement like "**for** constraint **pardo**" should only contain a contraint on the id's of the processors but not something complicated (like the color) which has to be checked and, hence, induces work. Because of the sorting we can transform this complicated constraint into a constraint on just the processor id's.

|--|

Lemma 9 A ring can be colored with 3 colors in time $O(\log n)$ and with work O(n). work optimal but not too fast

We need $O(\log \log n)$ shrinking iterations until the size of the remaining list reaches $O(n/\log n)$.

Each shrinking iteration takes time $O(\log n)$.

The work for all shrinking operations is just O(n), as the size of the list goes down by a constant factor in each round.

List Ranking can be solved in time $O(\log n \log \log n)$ and work O(n) on an EREW-PRAM.

Observations/Remarks:

- If the *p*-pointer of a block cannot be advanced without leaving the block, the processor responsible for this block simply stops working; all other blocks continue.
- The *p*-node of a block (the node *p_i* is pointing to) at the beginning of a round is either a ruler with a living subject or the node will become active during the round.
- The subject nodes always lie to the left of the *p*-node of the respective block (if it exists).

Measure of Progress:

- a ruler will delete a subject
- an active node either
 - becomes a ruler (with a subject)
 - becomes a subject
 - is isolated and therefore gets deleted

Optimal List Ranking

Each iteration requires constant time and work $\mathcal{O}(n/\log n)$, because we just work on one node in every block.

We need to prove that we just require $O(\log n)$ iterations to reduce the size of the list to $O(n/\log n)$.

PA © Harald Räcke

5 List Ranking

Analysis

For the analysis we assign a weight to every node in every block as follows.

Definition 10

PA ©Harald Räcke

The weight of the *i*-th node in a block is

 $(1 - q)^{i}$

with $q = \frac{1}{\log \log n}$, where the node-numbering starts from 0. Hence, a block has nodes $\{0, \dots, \log n - 1\}$.

```
PA
©Harald Räcke
```

5 List Ranking

Definition of Rulers

Properties:

- A ruler should have at most $\log \log n$ subjects.
- The weight of a ruler should be at most the weight of any of its subjects.
- Each ruler must have at least one subject.
- We must be able to remove the next subject in constant time.
- We need to make the ruler/subject decision in constant time.

| 5 List Banking | | |
|----------------------|----|--|
| לה PA 5 List Ranking | | |
| UUU G Harald Räcke | 78 | |

Now we change the ruler definition.

Consider some chain.

We make all local minima w.r.t. the weight function into a ruler; ties are broken according to block-id (so that comparing weights gives a strict inequality).

A ruler gets as subjects the nodes left of it until the next local maximum (or the start of the chain) (including the local maximum) and the nodes right of it until the next local maximum (or the end of the chain) (excluding the local maximum).

In case the first node is a ruler the above definition could leave it without a subject. We use constant time to fix this in some arbitrary manner

```
PA
©Harald Räcke
```

80

Given a sublist of active nodes.

Color the sublist with $\mathcal{O}(\log \log n)$ colors. Take the local minima w.r.t. this coloring.

If the first node is not a ruler

- if the second node is a ruler switch ruler status between first and second
- otw. just make the first node into a ruler

This partitions the sub-list into chains of length at most $\log \log n$ each starting with a ruler

PA ©Harald Räcke

5 List Ranking

79

Set $q = \frac{1}{\log \log n}$.

The *i*-th node in a block is assigned a weight of $(1 - q)^i$, $0 \le i < \log n$

The total weight of a block is at most 1/q and the total weight of all items is at most $\frac{n}{d \log n}$.

to show:

After $O(\log n)$ iterations the weight is at most $(n/\log n)(1-q)^{\log n}$

This means at most $n/\log n$ nodes remain because the smallest weight a node can have is $(1-q)^{\log n-1}$.

| In every iteration the weight drops by a factor of | In every iteration | the | weight | drops | by a | factor of |
|--|--------------------|-----|--------|-------|------|-----------|
|--|--------------------|-----|--------|-------|------|-----------|

(1 - q/4).

| | 5 List Ranking |
|------------------------|----------------|
| ∐ 💾 🛛 🖉 © Harald Räcke | |
| | |

82

The weight is reduced because

- An isolated node is removed.
- A node is labelled as ruler, and the corresponding subjects reduce their weight by a factor of 1/2.
- A node is a ruler and deletes one of its subjects.

Hence, the weight reduction comes from p-nodes (ruler/active).

We consider subject nodes to just have half their weight.

We can view the step of becoming a subject as a precursor to deletion.

Hence, a node looses half its weight when becoming a subject and the remaining half when deleted.

Note that subject nodes will be deleted after just an additional $O(\log \log n)$ iterations.

PA ©Harald Räcke

PA ©Harald Räcke 5 List Ranking

83

Each p-node is **responsible** for some other nodes; it has to generate a weight reduction large enough so that the weight of all nodes it is responsible for decreases by the desired factor.

An active node is responsible for all nodes that come after it in its block.

A ruler is responsible for all nodes that come after it in its block **and** for all its subjects.

Note that by this definition every node remaining in the list is covered.

Case 1: Isolated Node

Suppose we delete an isolated node v that is the *i*-th node in its block.

The weight of all node that v is responsible for is

$$\sum_{i \le j < \log n} (1-q)^j$$

This weight reduces to

$$\sum_{i < j < \log n} (1 - q)^j \le (1 - q) \sum_{i \le j < \log n} (1 - q)^j$$

Hence, weight reduces by a factor $(1 - q) \le (1 - q/4)$.

| החוחר | PA © Harald Räcke | |
|-------|----------------------|--|
| | © Harald Räcke | |

86

Case 3: Removing Subjects

weight of ruler: $(1-q)^{i_1}$; weight of subjects: $(1-q)^{i_j}$, $2 \le j \le k$

5 List Ranking

Assume ruler removes subject with largest weight say i_2 (why?).

Initial weight:

$$Q = \sum_{i_1 \le \ell < \log n} (1-q)^{\ell} + \frac{1}{2} \sum_{j=2}^k (1-q)^{i_j}$$

$$\le \frac{1}{q} (1-q)^{i_1} + \frac{k}{2} (1-q)^{i_2}$$

$$\le \frac{1}{q} (1-q)^{i_2} + \frac{1}{2q} (1-q)^{i_2}$$

New weight:

$$Q' = Q - \frac{1}{2}(1-q)^{i_2} \le (1-\frac{q}{3})Q$$

Case 2: Creating Subjects

Suppose we generate a ruler with at least one subject.

Weight of ruler: $(1-q)^{i_1}$. Weight of subjects: $(1-q)^{i_j}$, $2 \le j \le k$.

Initial weight:

$$Q = \sum_{j=1}^{k} \sum_{i_j \le \ell < \log n} (1-q)^{\ell} \le \frac{1}{q} \sum_{j=1}^{k} (1-q)^{i_j} \le \frac{2}{q} \sum_{j=2}^{k} (1-q)^{i_j}$$

New weight:

$$Q' = Q - \frac{1}{2} \sum_{j=2}^{k} (1-q)^{i_j} \le (1-\frac{q}{4})Q$$

After *s* iterations the weight is at most

$$\frac{n}{q\log n}\left(1-\frac{q}{4}\right)^s \stackrel{!}{\leq} \frac{n}{\log n}(1-q)^{\log n}$$

Choosing $i = 5 \log n$ the inequality holds for sufficiently large n.

6 Tree Algorithms

We want to apply rake operations to a binary tree T until T just consists of the root with two children.

Possible Problems:

- 1. we could concurrently apply the rake-operation to two siblings
- 2. we could concurrently apply the rake-operation to two leaves u and v such that p(u) and p(v) are connected

By choosing leaves carefully we ensure that none of the above cases occurs

| לח חח PA | 6 Tree Algorithms | |
|--------------------------|-------------------|----|
| 🛛 🕒 🖯 🕼 🛛 🖓 Harald Räcke | | 98 |
| | | |

Observations

- the rake operation does not change the order of leaves
- two leaves that are siblings do not perform a rake operation in the same round because one is even and one odd at the start of the round
- two leaves that have adjacent parents either have different parity (even/odd) or they differ in the type of child (left/right)

Algorithm:

- label leaves consecutively from left to right (excluding left-most and right-most leaf), and store them in an array A
- for $\lceil \log(n+1) \rceil$ iterations
 - apply rake to all odd leaves that are left children
 - apply rake operation to remaining odd leaves (odd at start of round!!!)
 - A=even leaves

PA ©Harald Räcke 6 Tree Algorithms 99

Evaluating Expressions

Suppose that we want to evaluate an expression tree, containing additions and multiplications.

- ► one iteration can be performed in constant time with O(|A|) processors, where A is the array of leaves;
- ▶ hence, all iterations can be performed in O(log n) time and O(n) work;
- ► the initial parallel prefix also requires time O(log n) and work O(n)

PA © Harald Räcke 6 Tree Algorithms

103

We can use the rake-operation to do this quickly.

Applying the rake-operation changes the tree.

In order to maintain the value we introduce parameters a_v and b_v for every node that still allows to compute the value of a node based on the value of its children.

Invariant:

Let u be internal node with children v and w. Then

 $\operatorname{val}(u) = (a_v \cdot \operatorname{val}(v) + b_v) \otimes (a_w \cdot \operatorname{val}(w) + b_w)$

where $\otimes \in \{*, +\}$ is the operation at node u.

Initially, we can choose $a_v = 1$ and $b_v = 0$ for every node.

If we change the a and b-values during a rake-operation according to the previous slide we can calculate the value of the root in the end.

Lemma 12

We can evaluate an arithmetic expression tree in time $O(\log n)$ and work O(n) regardless of the height or depth of the tree.

By performing the rake-operation in the reverse order we can also compute the value at each node in the tree.

Range Minima Problem

Given an array A[1...n], a range minimum query (ℓ, r) consists of a left index $\ell \in \{1, ..., n\}$ and a right index $r \in \{1, ..., n\}$.

The answer has to return the index of the minimum element in the subsequence $A[\ell \dots r]$.

The goal in the range minima problem is to preprocess the array such that range minima queries can be answered quickly (constant time).

PA ©Harald Räcke 6 Tree Algorithms

114

Observation

Given an algorithm for solving the range minima problem in time T(n) and work W(n) we can obtain an algorithm that solves the LCA-problem in time $\mathcal{O}(T(n) + \log n)$ and work $\mathcal{O}(n + W(n))$.

Remark

In the sequential setting the LCA-problem and the range minima problem are equivalent. This is not necessarily true in the parallel setting.

For solving the LCA-problem it is sufficient to solve the restricted range minima problem where two successive elements in the array just differ by +1 or -1.

PA ©Harald Räcke 6 Tree Algorithms

115

- Suppose we have an array A of length $n = 2^k$
- We compute a complete binary tree *T* with *n* leaves.
- Each internal node corresponds to a subsequence of *A*. It contains an array with the prefix and suffix minima of this subsequence.

Given the tree T we can answer a range minimum query (ℓ,r) in constant time.

- ► we can determine the LCA x of ℓ and r in constant time since T is a complete binary tree
- Then we consider the suffix minimum of ℓ in the left child of x and the prefix minimum of r in the right child of x.
- The minimum of these two values is the result.

Lemma 15

We can solve the range minima problem in time $O(\log n)$ and work $O(n \log n)$.

PA © Harald Räcke 6 Tree Algorithms

118

Answering a query (ℓ, r) :

- if l and r are from the same block the data-structure for this block gives us the result in constant time
- if ℓ and r are from different blocks the result is a minimum of three elements:
 - the suffix minmum of entry ℓ in ℓ 's block
 - the minimum among $x_{\ell+1}, \ldots, x_{r-1}$
 - the prefix minimum of entry *r* in *r*'s block

Reducing the Work

Partition A into blocks B_i of length $\log n$

Preprocess each B_i block separately by a sequential algorithm so that range-minima queries within the block can be answered in constant time. (how?)

For each block B_i compute the minimum x_i and its prefix and suffix minima.

Use the previous algorithm on the array $(x_1, \ldots, x_{n/\log n})$.

PA © Harald Räcke 6 Tree Algorithms

119

Searching

An extension of binary search with p processors gives that one can find the rank of an element in

$$\log_{p+1}(n) = \frac{\log n}{\log(p+1)}$$

many parallel steps with *p* processors. (not work-optimal)

This requires a CREW PRAM model. For the EREW model searching cannot be done faster than $O(\log n - \log p)$ with p processors even if there are p copies of the search key.

Merging

Given two sorted sequences $A = (a_1, \ldots, a_n)$ and $B = (b_1, \ldots, b_n)$, compute the sorted squence $C = (c_1, \ldots, c_n)$.

Definition 16

Let $X = (x_1, ..., x_t)$ be a sequence. The rank rank $(\gamma : X)$ of γ in X is

 $\operatorname{rank}(\gamma : X) = |\{x \in X \mid x \le \gamma\}|$

For a sequence $Y = (y_1, \dots, y_s)$ we define $\operatorname{rank}(Y : X) := (r_1, \dots, r_s)$ with $r_i = \operatorname{rank}(\gamma_i : X)$.

PA ©Harald Räcke PA

7 Searching and Sorting

122

Merging

We have already seen a merging-algorithm that runs in time $\mathcal{O}(\log n)$ and work $\mathcal{O}(n)$.

Using the fast search algorithm we can improve this to a running time of $\mathcal{O}(\log \log n)$ and work $\mathcal{O}(n \log \log n)$.

PA © Harald Räcke

7 Searching and Sorting

Merging

Input: $A = a_1, ..., a_n$; $B = b_1, ..., b_m$; $m \le n$

- 1. if m < 4 then rank elements of B, using the parallel search algorithm with *p* processors. Time: O(1). Work: O(n).
- **2.** Concurrently rank elements $b_{\sqrt{m}}, b_{2\sqrt{m}}, \ldots, b_m$ in A using the parallel search algorithm with $p = \sqrt{n}$. Time: O(1). Work: $\mathcal{O}(\sqrt{m} \cdot \sqrt{n}) = \mathcal{O}(n)$

 $j(i) := \operatorname{rank}(b_{i\sqrt{m}}:A)$

3. Let
$$B_i = (b_{i\sqrt{m}+1}, \dots, b_{(i+1)\sqrt{m}-1})$$
; and $A_i = (a_{j(i)+1}, \dots, a_{j(i+1)})$.

Recursively compute rank(B_i : A_i).

4. Let *k* be index not a multiple of \sqrt{m} . $i = \lfloor \frac{k}{\sqrt{m}} \rfloor$. Then $\operatorname{rank}(b_k:A) = j(i) + \operatorname{rank}(b_k:A_i).$

Mergesort

Lemma 17

A straightforward parallelization of Mergesort can be implemented in time $O(\log n \log \log n)$ and with work $O(n \log n)$.

This assumes the CREW-PRAM model.

PA © Harald Räcke | PA

7 Searching and Sorting

Pipelined Mergesort

We again compute L[v] for every node in the complete binary tree.

After round *s*, $L_s[v]$ is an **approximation** of L[v] that will be improved in future rounds.

```
For s \ge 3 height(v), L_s[v] = L[v].
```

Mergesort

Let L[v] denote the (sorted) sublist of elements stored at the leaf nodes rooted at v_{\perp}

We can view Mergesort as computing L[v] for a complete binary tree where the leaf nodes correspond to nodes in the given array.

Since the merge-operations on one level of the complete binary tree can be performed in parallel we obtain time $O(h \log \log n)$ and work $\mathcal{O}(hn)$, where $h = \mathcal{O}(\log n)$ is the height of the tree.

PA ©Harald Räcke

Definition 28

PA ©Harald Räcke

A 0-1 sequence S is bitonic if it can be written as the concatenation of subsequences S_1 and S_2 such that either

- S₁ is monotonically increasing and S₂ monotonically decreasing, or
- S₁ is monotonically decreasing and S₂ monotonically increasing.

Note, that this just defines bitonic 0-1 sequences. Bitonic sequences are defined differently.

```
PA
© Harald Räcke
```

7 Searching and Sorting

142

Bitonic Merger

If we feed a bitonic 0-1 sequence S into the network on the right we obtain two bitonic sequences S_T and S_B s.t.

- **1.** $S_B \leq S_T$ (element-wise)
- **2.** S_B and S_T are bitonic

Proof:

- ► assume wlog. *S* more 1's than 0's.
- ► assume for contradiction two 0s at same comparator $(i, j = i + 2^d)$
 - everything 0 btw *i* and *j* means we have more than 50% zeros (*i*).
 - all 1s btw. *i* and *j* means we have less than 50% ones (*i*).
 - 1 btw. *i* and *j* and elsewhere means *S* is not bitonic (*f*).

Bitonic Merger

Bitonic Merger *B*_d

The bitonic merger B_d of dimension d is constructed by combining two bitonic mergers of dimension d - 1.

If we feed a bitonic 0-1 sequence into this, the sequence will be sorted.

(actually, any bitonic sequence will be sorted, but we do not prove this)

Bitonic Merger: $(n = 2^d)$

- comparators: $C(n) = 2C(n/2) + n/2 \Rightarrow C(n) = O(n \log n)$.
- depth: $D(n) = D(n/2) + 1 \Rightarrow D(d) = O(\log n)$.

Bitonic Sorter: $(n = 2^d)$

- comparators: $C(n) = 2C(n/2) + O(n\log n) \Rightarrow$ $C(n) = O(n\log^2 n).$
- depth: $D(n) = D(n/2) + \log n \Rightarrow D(n) = \Theta(\log^2 n)$.

Odd-Even Merge

How to merge two sorted sequences?

 $A = (a_1, a_2, \dots, a_n), B = (b_1, b_2, \dots, b_n), n$ even.

Split into odd and even sequences:

 $A_{\text{odd}} = (a_1, a_3, a_5, \dots, a_{n-1}), A_{\text{even}} = (a_2, a_4, a_6, \dots, a_n)$ $B_{\text{odd}} = (b_1, b_3, b_5, \dots, b_{n-1}), B_{\text{even}} = (b_2, b_4, b_6, \dots, b_n)$

Let

 $X = merge(A_{odd}, B_{odd})$ and $Y = merge(A_{even}, B_{even})$

Then

 $S = (x_1, \min\{x_2, y_1\}, \max\{x_2, y_1\}, \min\{x_3, y_2\}, \dots, y_n)$

| 🛛 🕒 🛛 🖉 @ Harald Räcke | |

between PRAMs

Let $U = \{u_1, ..., u_r\}$ denote all indices that cause some processor to write into M.

Let $V = \{(I(u_1), P_{w_1}), \dots\}.$

We set up a bipartite graph between U and V, such that $(u_i, (I(u_j), P_{w_j})) \in E$ if u_i affects P_{w_j} at time t + 1 on input $I(u_j)$.

Each vertex $(I(u_j), P_{w_j})$ has degree at most k_{t+1} as this is an upper bound on indices that can influence a processor P_{w_j} .

Hence, $|E| \leq r \cdot k_{t+1}$.

Y(M, t + 1, I) is the set of indices u_j that cause some processor P_{w_j} to write into M at time t + 1 on input I.

Fact:

For all pairs u_s , u_t with $P_{w_s} \neq P_{w_t}$ either $u_s \in K(P_{w_t}, t+1, I(u_t))$ or $u_t \in K(P_{w_s}, t+1, I(u_s))$.

Otherwise, P_{w_t} and P_{w_s} would both write into M at the same time on input $I(u_s)(u_t)$.

PA ©Harald Räcke

10 Simulations between PRAMs

For an index u_j there can be at most k_{t+1} indices u_i with $P_{w_i} = P_{w_j}$.

Hence, there must be at least $\frac{1}{2}r(r-k_{t+1})$ pairs u_i, u_j with $P_{w_i} \neq P_{w_j}$.

Each pair introduces at least one edge.

Hence,

PA ©Harald Räcke $|E| \geq \frac{1}{2}r(r-k_{t+1})$

This gives $r \leq 3k_{t+1} \leq 3k_t + 3\ell_t$

PA © Harald Räcke 10 Simulations between PRAMs

182

Recall that
$$L(M, t + 1, i) \subseteq L(M, t, i) \cup Y(M, t + 1, I)$$

 $|L(M, t + 1, i)| \leq 3k_t + 4\ell_t$

$$v_{1} = \begin{pmatrix} 1\\ \frac{3}{2} + \frac{1}{2}\sqrt{21} \end{pmatrix} \text{ and } v_{2} = \begin{pmatrix} 1\\ \frac{3}{2} - \frac{1}{2}\sqrt{21} \end{pmatrix}$$
$$\begin{pmatrix} k_{0}\\ \ell_{0} \end{pmatrix} = \begin{pmatrix} 0\\ 1 \end{pmatrix} = \frac{1}{\sqrt{21}}(v_{1} - v_{2})$$
$$\begin{pmatrix} k_{t}\\ \ell_{t} \end{pmatrix} = \frac{1}{\sqrt{21}}(\lambda_{1}^{t}v_{1} - \lambda_{2}^{t}v_{2})$$

$$\begin{pmatrix} k_{t+1} \\ \ell_{t+1} \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 3 & 4 \end{pmatrix} \begin{pmatrix} k_t \\ \ell_t \end{pmatrix} \qquad \begin{pmatrix} k_0 \\ \ell_0 \end{pmatrix} = \begin{pmatrix} 0 \\ 1 \end{pmatrix}$$

Eigenvalues:

$$\lambda_1 = \frac{1}{2}(5 + \sqrt{21}) \text{ and } \lambda_2 = \frac{1}{2}(5 - \sqrt{21})$$

Eigenvectors:

$$v_1 = \begin{pmatrix} 1\\ -(1-\lambda_1) \end{pmatrix}$$
 and $v_2 = \begin{pmatrix} 1\\ -(1-\lambda_2) \end{pmatrix}$
 $v_1 = \begin{pmatrix} 1\\ \frac{3}{2} + \frac{1}{2}\sqrt{21} \end{pmatrix}$ and $v_2 = \begin{pmatrix} 1\\ \frac{3}{2} - \frac{1}{2}\sqrt{21} \end{pmatrix}$

Solving the recurrence gives

$$k_t = \frac{\lambda_1^t}{\sqrt{21}} - \frac{\lambda_2^t}{\sqrt{21}}$$
$$\ell_t = \frac{3 + \sqrt{21}}{2\sqrt{21}}\lambda_1^t + \frac{-3 + \sqrt{21}}{2\sqrt{21}}\lambda_2^t$$
with $\lambda_1 = \frac{1}{2}(5 + \sqrt{21})$ and $\lambda_2 = \frac{1}{2}(5 - \sqrt{21})$.

Theorem 47

The following problems require logarithmic time on a CREW PRAM.

- Sorting a sequence of x_1, \ldots, x_n with $x_i \in \{0, 1\}$
- \blacktriangleright Computing the maximum of *n* inputs
- Computing the sum $x_1 + \cdots + x_n$ with $x_i \in \{0, 1\}$

| | 10 Simulations between PRAMs | |
|------------------|------------------------------|-----|
| UUU©Harald Räcke | | 190 |

Let I_i be the input with *i* zeros folled by n - i ones.

Index i affects processor P at time t if the state in step t is differs between I_{i-1} and I_i .

Index *i* affects location M at time t if the content of M after step t differs between inputs I_{i-1} and I_i .

Definition 48 (Zero Counting Problem)

Given a monotone binary sequence x_1, x_2, \ldots, x_n determine the index *i* such that $x_i = 0$ and $x_{i+1} = 1$.

We show that this problem requires $\Omega(\log n - \log p)$ steps on a *p*-processor EREW PRAM.

PA © Harald Räcke

10 Simulations between PRAMs

Lemma 50

If $i \in L(M, t)$ then either

- ▶ $i \in L(M, t 1)$, or
- Some processor P writes M at step t on input I_i and $i \in K(P, t)$.
- Some processor P writes M at step t on input I_{i-1} and $i \in K(P, t)$.

| PA © Harald Räcke | 10 Simulations between PRAMs | 194 |
|----------------------|------------------------------|-----|

For an index i to newly appear in L(M, t) some processor must write into M on either input I_i or I_{i-1} .

Hence, any index in K(P, t) can at most generate two new indices in L(M, t).

This means that the number of new indices in any set L(M, t) (over all M) is at most

$$2\sum_{P}|K(P,t)|$$

PA © Harald Räcke 10 Simulations between PRAMs

196

$$C(t) = \sum_{P} |K(P,t)| + \sum_{M} \max\{0, |L(M,t)| - 1\}$$

 $C(T) \ge n, C(0) = 0$

Claim: $C(t) \le 6C(t-1) + 3|P|$

This gives $C(T) \leq \frac{6^T - 1}{5} 3|P|$ and hence $T = \Omega(\log n - \log |P|)$.

10 Simulations between PRAMs

Hence,

$$\sum_{M} |L(M,t)| \le \sum_{M} |L(M,t-1)| + 2\sum_{P} |K(P,t)|$$

We can assume wlog. that $L(M, t - 1) \subseteq L(M, t)$. Then

$$\sum_{M} \max\{0, |L(M,t)| - 1\} \le \sum_{M} \max\{0, |L(M,t-1)| - 1\} + 2\sum_{P} |K(P,t)|$$

PA © Harald Räcke

10 Simulations between PRAMs

For an index i to newly appear in K(P, t), P must read a memory location M with $i \in L(M, t)$ on input I_i (and also on input I_{i-1}).

Since we are in the EREW model at most one processor can do so in every step.

Let J(i, t) be memory locations read in step t on input I_i , and let $J_t = \bigcup_i J(i, t)$.

$$\sum_{P} |K(P,t)| \le \sum_{P} |K(P,t-1)| + \sum_{M \in J_t} |L(M,t-1)|$$

Over all inputs I_i a processor can read at most |K(P, t - 1)| + 1 different memory locations (why?).

| | 10 Simulations between PRAMs | | |
|------------------------|------------------------------|-----|--|
| 🛛 💾 🛛 🖉 @ Harald Räcke | | 198 | |

This gives

$$\sum_{P} K(P,t) + \sum_{M} \max\{0, |L(M,t)| - 1\}$$

$$\leq 4 \sum_{M} \max\{0, |L(M,t-1)| - 1\} + 6 \sum_{P} |K(P,t-1)| + 3|P$$

Hence,

$$C(t) \le 6C(t-1) + 3|P|$$

PA ©Harald Räcke 10 Simulations between PRAMs

Hence,

$$\begin{split} \sum_{P} |K(P,t)| &\leq \sum_{P} |K(P,t-1)| + \sum_{M \in J_{t}} |L(M,t-1)| \\ &\leq \sum_{P} |K(P,t-1)| + \sum_{M \in J_{t}} (|L(M,t-1)|-1) + J_{t} \\ &\leq 2 \sum_{P} |K(P,t-1)| + \sum_{M \in J_{t}} (|L(M,t-1)|-1) + |P| \\ &\leq 2 \sum_{P} |K(P,t-1)| + \sum_{M} \max\{0, |L(M,t-1)|-1\} + |P| \end{split}$$

Recall

$$\sum_{M} \max\{0, |L(M,t)| - 1\} \le \sum_{M} \max\{0, |L(M,t-1)| - 1\} + 2\sum_{P} |K(P,t)|$$

Lower Bounds for CRCW PRAMS

Theorem 51

Let $f: \{0,1\}^n \rightarrow \{0,1\}$ be an arbitrary Boolean function. f can be computed in $\mathcal{O}(1)$ time on a common CRCW PRAM with $\leq n2^n$ processors.

Can we obtain non-constant lower bounds if we restrict the number of processors to be polynomial?

Boolean Circuits

| nodes are either AND, OR, or NOT gates or are special |
|---|
| INPUT/OUTPUT nodes |

- AND and OR gates have unbounded fan-in (indegree) and ounbounded fan-out (outdegree)
- NOT gates have unbounded fan-out
- INPUT nodes have indegree zero; OUTPUT nodes have outdegree zero
- size is the number of edges
- depth is the longest path from an input to an output

| | 10 Simulations between PRAMs | |
|------------------------|------------------------------|-----|
| 🛛 💾 🛛 🖉 © Harald Räcke | | 202 |

Given a family $\{C_n\}$ of circuits we may not be able to compute the corresponding family of functions on a CRCW PRAM.

Definition 53

A family $\{C_n\}$ of circuits is logspace uniform if there exists a deterministic Turing machine M s.t

- ► *M* runs in logarithmic space.
- For all n, M outputs C_n on input 1^n .

PA ©Harald Räcke

<image>

Permutation Routing

base case d = 0trivial

induction step $d \rightarrow d + 1$

- The packets that start at (ā, d) and (ā(d), d) have to be sent into different sub-networks.
- ► The packets that end at (ā, -d) and (ā(d), -d) have to come out of different sub-networks.

We can generate a graph on the set of packets.

- Every packet has an incident source edge (connecting it to the conflicting start packet)
- Every packet has an incident target edge (connecting it to the conflicting packet at its target)
- This clearly gives a bipartite graph; Coloring this graph tells us which packet to send into which sub-network.

Permutation Routing on the n-ary Beneš Network

Instead of two we have n sub-networks B(n, d - 1).

All packets starting at positions $\{(x_0, \ldots, x_{d-2}, x_{d-1}, d) \mid x_{d-1} \in [n]\}$ have to be send to different sub-networks.

All packets ending at positions $\{(x_0, \ldots, x_{d-2}, x_{d-1}, d) \mid x_{d-1} \in [n]\}$ have to come from different sub-networks.

The conflict graph is an n-uniform 2-regular hypergraph.

We can color such a graph with n colors such that no two nodes in a hyperedge share a color.

This gives the routing.

Lemma 56

On a d-dimensional mesh with sidelength n we can route any permutation (offline) in 4dn steps.

We can simulate the algorithm for the n-ary Beneš Network.

Each step can be simulated by routing on disjoint linear arrays. This takes at most 2n steps.

We simulate the behaviour of the Beneš network on the n-dimensional mesh.

In round $r \in \{-d, ..., -1, 0, 1, ..., d - 1\}$ we simulate the step of sending from level r of the Beneš network to level r + 1.

Each node $\bar{x} \in [n]^d$ of the mesh simulates the node (r, \bar{x}) .

Hence, if in the Beneš network we send from (r, \bar{x}) to $(r + 1, \bar{x}')$ we have to send from \bar{x} to \bar{x}' in the mesh.

All communication is performed along linear arrays. In round r < 0 the linear arrays along dimension -r - 1 (recall that dimensions are numbered from 0 to d - 1) are used

$$\bar{x}_{d-1}\ldots\bar{x}_{-r}\alpha\bar{x}_{-r-2}\ldots\bar{x}_0$$

In rounds $r \ge 0$ linear arrays along dimension r are used.

Hence, we can perform a round in $\mathcal{O}(n)$ steps.

The nodes are of the form $(\ell, \bar{x}), \bar{x} \in [n]^d, \ell \in -d, \dots, d$.

We can view nodes with same first coordinate forming columns and nodes with the same second coordinate as forming rows. This gives rows of length 2d - 1 and columns of length n^d .

We route in 3 phases:

- Permute packets along the rows such that afterwards no column contains packets that have the same target row. O(d) steps.
- **2.** We can use pipeling to permute **every** column, so that afterwards every packet is in its target row. O(2d + 2d) steps.
- **3.** Every packet is in its target row. Permute packets to their right destinations. O(d) steps.

Lemma 57

We can route any permutation on the Beneš network in $\mathcal{O}(d)$ steps with constant buffer size.

The same is true for the butterfly network.

Simulations between Networks

Definition 63

A configuration C_i of processor P_i is the complete description of the state of P_i including local memory, program counter, read-register, write-register, etc.

Suppose a machine *M* is in configuration $(C_0, ..., C_{p-1})$, performs *t* synchronous steps, and is then in configuration $C = (C'_0, ..., C'_{p-1})$.

 C'_i is called the *t*-th successor configuration of *C* for processor *i*.

Simulations between Networks

For the following observations we need to make the definition of parallel computer networks more precise.

Each node of a given network corresponds to a processor/RAM.

In addition each processor has a read register and a write register.

In one (synchronous) step each neighbour of a processor P_i can write into P_i 's write register or can read from P_i 's read register.

Usually we assume that proper care has to be taken to avoid concurrent reads and concurrent writes from/to the same register.

Suppose we allow concurrent reads, this means in every step all neighbours of a processor P_i can read P_i 's read register.

Lemma 69

A constant degree network *M* that can simulate any *n*-node network has slowdown $\Omega(\log n)$ (independent of the size of *M*).

Lemma 68

There is a constant degree network on $\mathcal{O}(n^{1+\epsilon})$ nodes that can simulate any constant degree network with slowdown $\mathcal{O}(1)$.

PA © Harald Räcke

PA © Harald Räcke 11 Some Networks

239

We show the lemma for the following type of simulation.

- There are representative sets A^t_i for every step t that specify which processors of M simulate processor P_i in step t (know the configuration of P_i after the t-th step).
- > The representative sets for different processors are disjoint.
- for all $i \in \{1, \ldots, n\}$ and steps $t, A_i^t \neq \emptyset$.

This is a step-by-step simulation.

Suppose processor P_i reads from processor P_{j_i} in step t.

Every processor $Q \in M$ with $Q \in A_i^{t+1}$ must have a path to a processor $Q' \in A_i^t$ and to $Q'' \in A_{j_i}^t$.

Let k_t be the largest distance (maximized over all i, j_i).

Then the simulation of step t takes time at least k_t .

The slowdown is at least

$$k = \frac{1}{\ell} \sum_{t=1}^{\ell} k_t$$

PA © Harald Räcke 11 Some Networks

242

Suppose there is no pair (i, j) such that i reading from j requires time $\gamma \log n$.

- For every *i* the set $\Gamma_{2k}(A_i)$ contains a node from A_i .
- Hence, there must exist a j_i such that $\Gamma_{2k}(A_i)$ contains at most

$$|C_{j_i}| := \frac{|A_i| \cdot c^{2k}}{n-1} \le \frac{|A_i| \cdot c^{3k}}{n}$$

processors from $|A_{j_i}|$

PA ©Harald Räcke 11 Some Networks

244

We show

- The simulation of a step takes at least time $\gamma \log n$, or
- the size of the representative sets shrinks by a lot

$$\sum_{i} |A_i^{t+1}| \le \frac{1}{n^{\epsilon}} \sum_{i} |A_i^t|$$

| הח) [הח] PA | 11 Some Networks | |
|--------------------|------------------|-----|
| UUU © Harald Räcke | | 243 |

If we choose that *i* reads from j_i we get

$$\begin{split} |A_i'| &\leq |C_{j_i}| \cdot c^k \\ &\leq c^k \cdot \frac{|A_i| \cdot c^{3k}}{n} \\ &= \frac{1}{n} |A_i| \cdot c^{4k} \end{split}$$

Choosing $k = \Theta(\log n)$ gives that this is at most $|A_i|/n^{\epsilon}$.

PA ©Harald Räcke Let ℓ be the total number of steps and s be the number of short steps when $k_t < \gamma \log n$.

In a step of time k_t a representative set can at most increase by c^{k_t+1} .

Let h_{ℓ} denote the number of representatives after step ℓ .

PA © Harald Räcke

Theorem 78 (Borodin, Hopcroft)

For any path system W there exists a permutation $\pi : V \to V$ and an edge $e \in E$ such that at least $\Omega(\sqrt{n}/\Delta)$ of the paths go through e.

Let
$$\mathcal{W}_{v} = \{P_{v,u} \mid u \in V\}$$
.
We say that an edge *e* is *z*-popular for *v* if at least *z* paths from \mathcal{W}_{v} contain *e*.

Lemma 79 Let $z \leq \frac{n-1}{\Delta}$.

For every node $v \in V$ there exist at least $\frac{n}{2\Delta z}$ edges that are z popular for v. This means

$$A_{v}(z) \ge \frac{n}{2\Delta z}$$

PA ©Harald Räcke

11 Some Networks

256

For any node v there are many edges that are are quite popular for v.

 $|V| \times |E|$ -matrix A(z):

$$A_{v,e}(z) = \begin{cases} 1 & e \text{ is } z \text{-popular for } v \\ 0 & \text{otherwise} \end{cases}$$

PA © Harald Räcke

$$A_{v}(z) = \sum_{e} A_{v,e}(z)$$
$$A_{e}(z) = \sum_{v} A_{v,e}(z)$$

11 Some Networks

Lemma 80

There exists an edge e' that is z-popular for at least z nodes with $z = \Omega(\sqrt{n}\Delta)$.

$$\sum_{e} A_{e}(z) = \sum_{v} A_{v}(z) \ge \frac{n^{2}}{2\Delta z}$$

There must exist an edge e'

$$A_{e'}(z) \ge \left\lceil \frac{n^2}{|E| \cdot 2\Delta z} \right\rceil \ge \left\lceil \frac{n}{2\Delta^2 z} \right\rceil$$

11 Some Networks

where the last step follows from $|E| \leq \Delta n$.

PA © Harald Räcke

We choose z such that $z = \frac{n}{2\Delta^2 z}$ (i.e., $z = \sqrt{n}/(\sqrt{2}\Delta)$).

This means e' is [z]-popular for [z] nodes.

We can construct a permutation such that z paths go through e'.

Expected number of packets: E[packets over v] = $p \cdot 2^i \cdot \frac{1}{2^i} = p$ since only $p2^i$ packets can reach v. But this is trivial. PA ©Harald Räcke 11 Some Networks

What is the probability that at least r packets go through v.

Pr[at least
$$r$$
 path through v] $\leq {\binom{p \cdot 2^i}{r}} \cdot {\left(\frac{1}{2^i}\right)^r}$
 $\leq {\left(\frac{p2^i \cdot e}{r}\right)^r} \cdot {\left(\frac{1}{2^i}\right)}$
 $= {\left(\frac{pe}{r}\right)^r}$

Pr[there exists a node v sucht that at least r path through v]

 $\leq d2^d \cdot \left(\frac{pe}{r}\right)^r$

PA ©Harald Räcke 11 Some Networks

262

 $\Pr[\text{there exists a node } v \text{ sucht that at least } r \text{ path through } v]$

$$\leq d2^d \cdot \left(\frac{pe}{r}\right)^2$$

Choose r as $2ep + (\ell + 1)d + \log d = \mathcal{O}(p + \log N)$, where N is number of sources in BF(d).

Pr[exists node v with more than r paths over $v] \le \frac{1}{N^{\ell}}$

We say a formal delay sequence is active if $rank(P_i) = k_i$ holds for all *i*.

Let N_s be the number of formal delay sequences of length at most s. Then

$$\Pr[\text{routing needs at least } d + s \text{ steps}] \le \frac{N_s}{k^{s+1}}$$

Definition 82 (Formal Delay Sequence)

- \blacktriangleright a path ${\mathcal W}$ of length d from a source to a target
- *s* integers $\ell_0 \ge 1$, $\ell_1, \dots, \ell_s \ge 0$ and $\sum_{i=0}^s \ell_i = d$
- nodes $v_0, \ldots v_s, v_{s+1}$ on \mathcal{W} with v_i being on level $d \ell_0 \cdots \ell_{i-1}$
- ▶ s + 1 packets $P_0, ..., P_s$, where P_i is a packet with path through v_i and v_{i-1}
- numbers $R_s \leq R_{s-1} \leq \cdots \leq R_0$

11 Some Networks

Hence the probability that the routing takes more than d + s steps is at most

$$N^3 \cdot \left(\frac{2e \cdot C \cdot (s+k)}{(s+1)k}\right)^{s+1}$$

We choose $s = 8eC - 1 + (\ell + 3)d$ and k = s + 1. This gives that the probability is at most $\frac{1}{N^{\ell}}$.

Valiants Trick

Where did the scheduling analysis use the butterfly?

We only used

- \blacktriangleright all routing paths are of the same length d
- there are a polynomial number of delay paths

Choose paths as follows:

- route from source to random destination on target level
- route to real target column (albeit on source level)
- route to target

All phases run in time $\mathcal{O}(p+d)$ with high probability.

270

- ▶ With probability $1 \frac{1}{N^{\ell_1}}$ the random routing problem has congestion at most $\mathcal{O}(p + \ell_1 d)$.
- With probability $1 \frac{1}{N^{\ell_2}}$ the packet scheduling finishes in at most $\mathcal{O}(C + \ell_2 d)$ steps.

Hence, with high probability routing random problems with p packets per source in a butterfly requires only O(p + d) steps.

What do we do for arbitrary routing problems?

Valiants Trick

A Balanced Multicommodity Flow Problem is a concurrent multicommodity flow problem in which incoming and outgoing flow is equal to

$$c(v) = \sum_{e=(v,x)\in E} c(e)$$

| PA ©Harald Räcke | 11 Some Networks 2 | 74 |
|---------------------|--------------------|----|
| | | |

For a network G = (V, E, c) we define the characteristic flow problem via

• demands $d_{u,v} = \frac{c(u)c(v)}{c(V)}$

Suppose the characteristic flow problem has a solution *S* with $C(S) \le F$ and $D(S) \le F$.

276

Valiants Trick

For a multicommodity flow S we assume that we have a decomposition of the flow(s) into flow-paths.

We use C(S) to denote the congestion of the flow problem (inverse of througput fraction), and D(S) the length of the longest routing path.

Definition 84

A (randomized) oblivious routing scheme is given by a path system \mathcal{P} and a weight function w such that

$$\sum_{p\in\mathcal{P}_{s,t}}w(p)=1$$

11 Some Networks

Construct an oblivious routing scheme from *S* as follows:

• let $f_{x,y}$ be the flow between x and y in S

$$f_{x,y} \ge d_{x,y}/C(S) \ge d_{x,y}/F = \frac{1}{F} \frac{c(x)c(y)}{c(V)}$$

• for
$$p \in \mathcal{P}_{x,y}$$
 set $w(p) = f_p/f_{x,y}$

gives an oblivious routing scheme.

| PA © Harald Räcke | 11 Some Networks |
|----------------------|------------------|
| | |

Valiants Trick

We apply this routing scheme twice:

- ► first choose a path from $\mathcal{P}_{s,v}$, where v is chosen uniformly according to c(v)/c(V)
- then choose path according to $\mathcal{P}_{v,t}$

If the input flow problem/packet routing problem is balanced doing this randomization results in flow solution S (twice).

Hence, we have an oblivious scheme with congestion and dilation at most 2F for (balanced inputs).

Oblivious Routing for the Mesh

We can route any permutation on an $n \times n$ mesh in $\mathcal{O}(n)$ steps, by *x*-*y* routing. Actually $\mathcal{O}(d)$ steps where *d* is the largest distance between a source-target pair.

What happens if we do not have a permutation?

x - y routing may generate large congestion if some pairs have a lot of packets.

Valiants trick may create a large dilation.

Let for a multicommodity flow problem $P C_{opt}(P)$ be the optimum congestion, and $D_{opt}(P)$ be the optimum dilation (by perhaps different flow solutions).

Lemma 85

There is an oblivious routing scheme for the mesh that obtains a flow solution S with $C(S) = O(C_{opt}(P) \log n)$ and $D(S) = O(D_{opt}(P))$.

| | 11 Some Networks | |

| | | |

Lemma 86

For any oblivious routing scheme on the mesh there is a demand *P* such that routing *P* will give congestion $\Omega(\log n \cdot C_{opt})$.
